

Relationships

is-a relationship:- one class is using a properties and beh of another class with inheritance

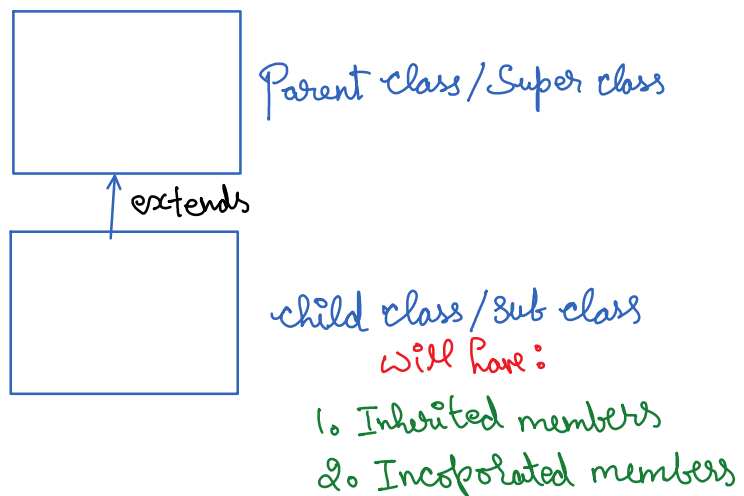

ex:-all the properties of emp class inherited to testing class

has-a relationship :-one class is using a properties and behavior of another class without inheritance

ex:-encapsulated class and driver class

Inheritance

Taking all the properties and behavior of super class to a sub class by using extends keyword is called as inheritance

super class:-class which is providing all the properties and behaviors to a child class

sub class:-class which is inheriting members from a super class

we are inheriting by using extends keyword

extends

syntax

class sub_class_name extends super_class_name

explanation :- all the properties and behavior of super class is inherited to sub class

NOTE:-if class doesn't extends any class then by default compiler will extend Object class

note

constructor calling statement

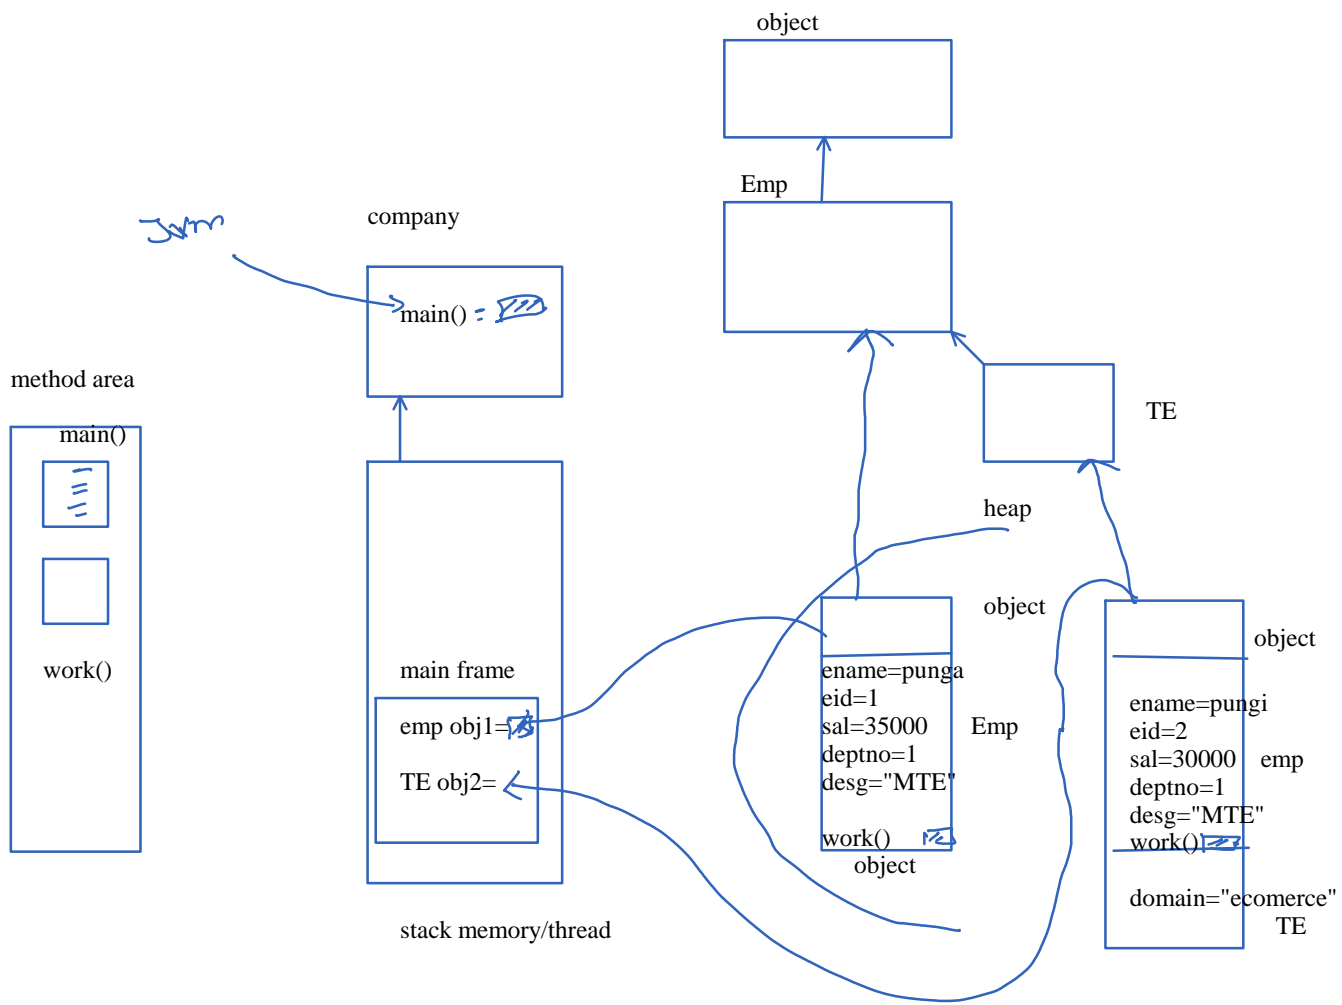

this():-to call the constructor of same class

super():-to call the constructor immediate parent class constructor

- 1)one constructor can contain either one this() or one super()
- 2)CCS should be declared at the beginning
- 3)when there is no CCS then by default compiler will add super()
- 4)to use super() extends is mandatory(to use super()-classes should follow is-a relationship)

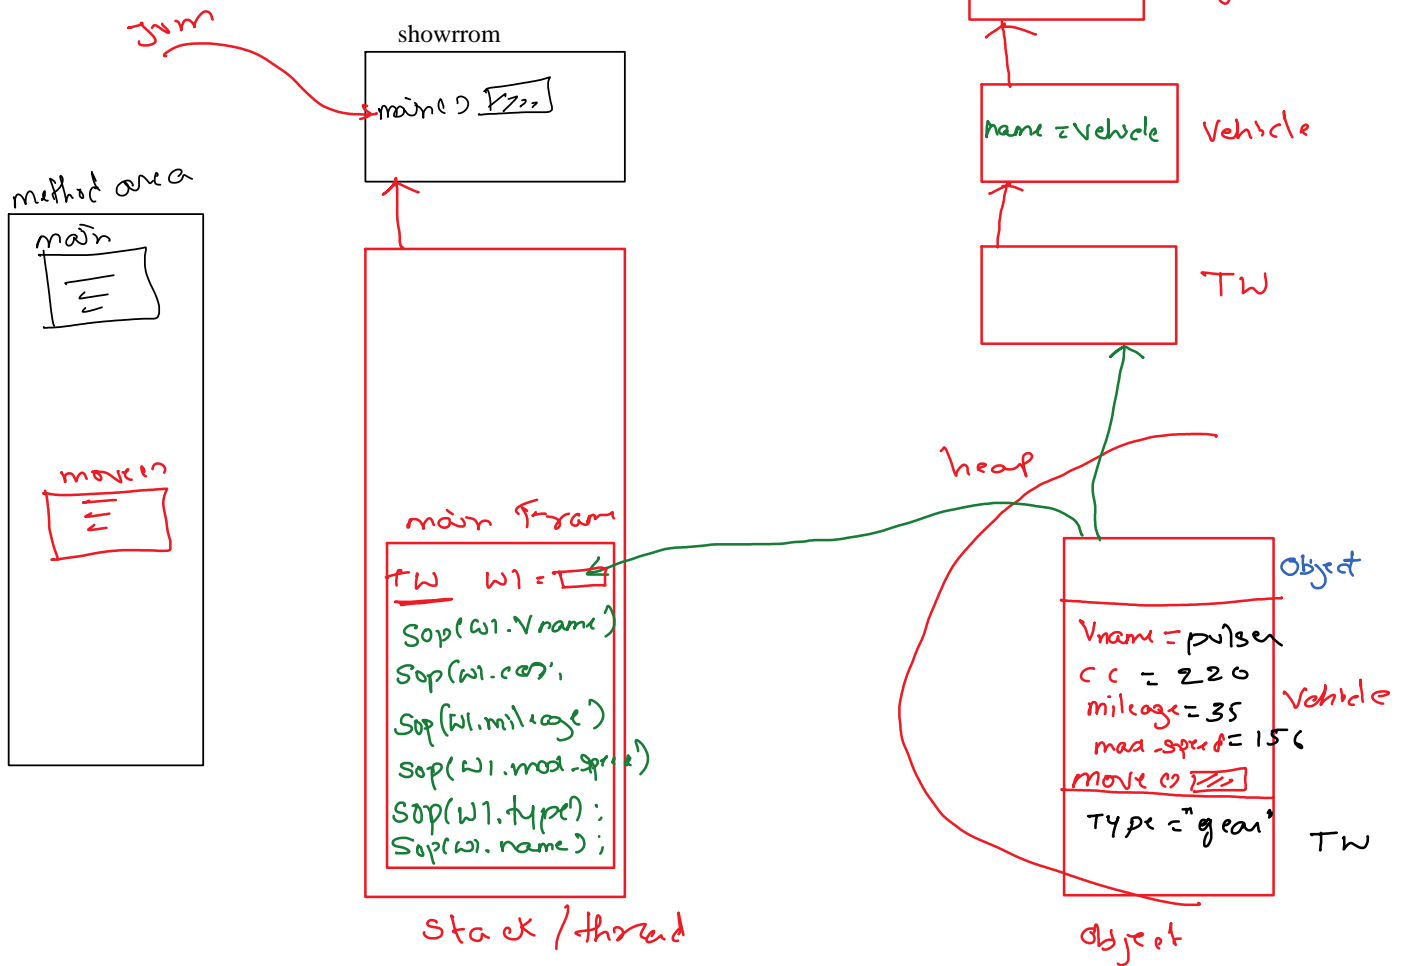

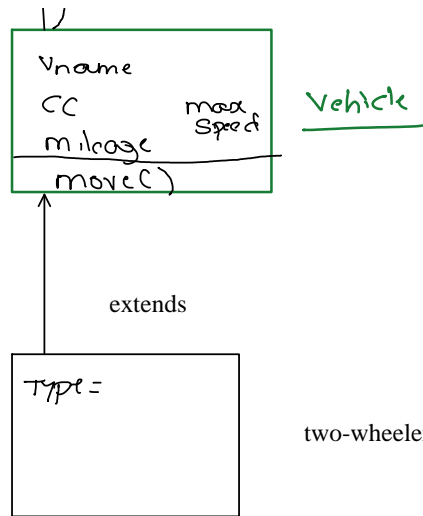

Ex

C2-2

o/p
pulser

220

is it possible to inherit static members ? yes we can

extends keyword can inherit static and non static members

imp

prove that static members also inheritable by using extends?

Assignment - 1

driver:- school

create an object for HSS and PSS

Type of inheritance by using extends keyword

single level inheritance

multi level inheritance

hierarchical inheritance

multiple inheritance

not possible by using extends → implements
interface

hybrid /derived inheritance

Sub

by using extends we can't achieve hybrid
we can achieve through implements (interface)

super keyword : it is used to access a members of super class

we can't use super inside static context ,

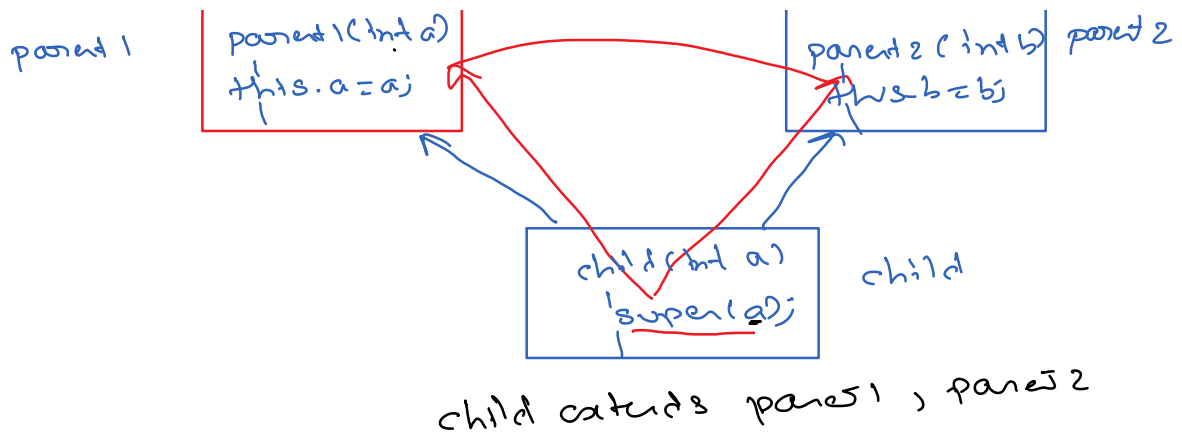

Diamond problem

Reason 1 super();

Reason -2 Same const in a parent classes

Reason - 3

we can
solve
by using

Diamond problem :- it is a major problem occurs when we try to inherit more than one parent/super classes

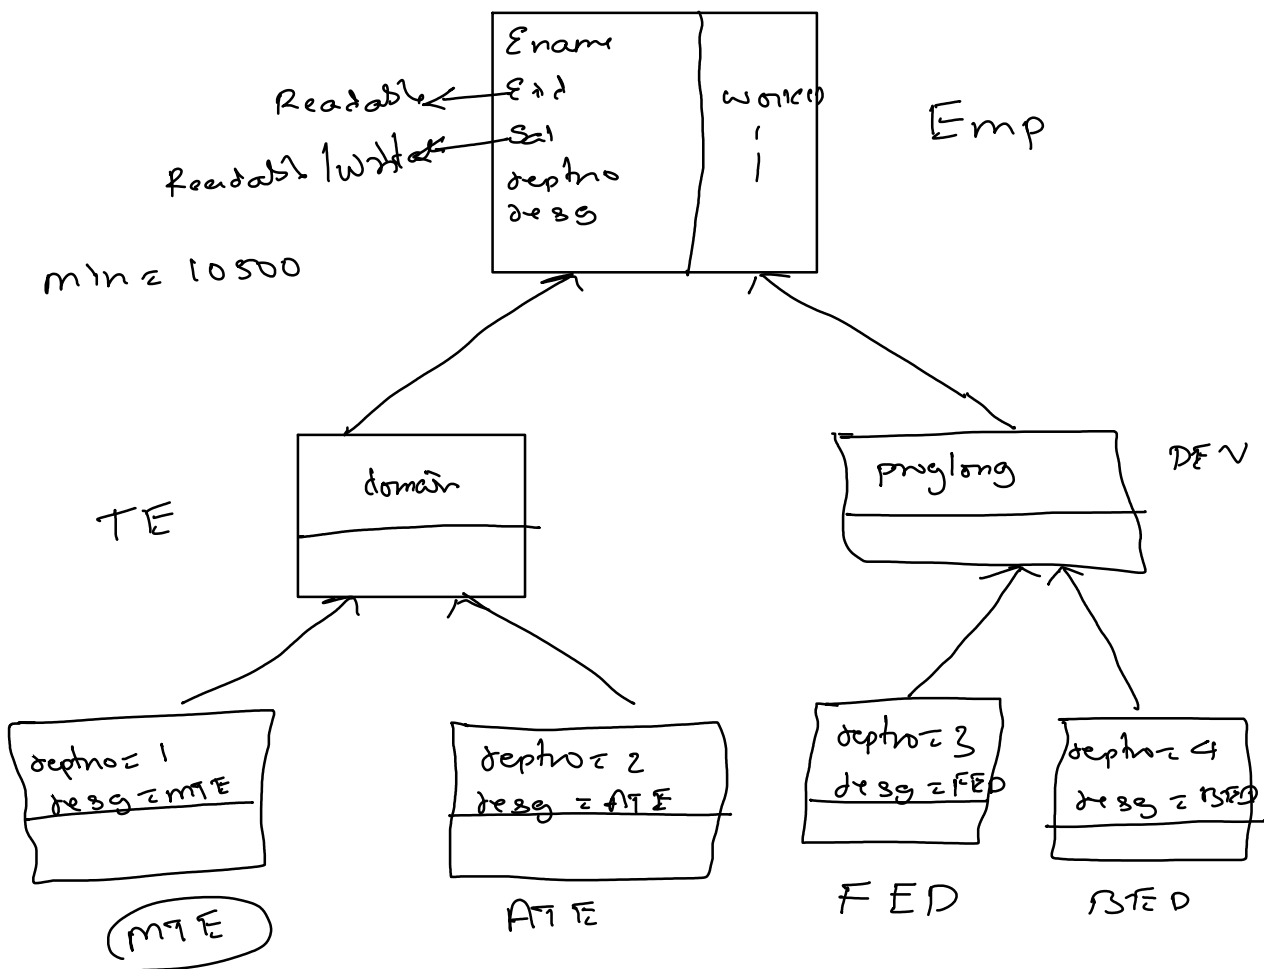

problem-1 if both parent class contains default constructor and if sub class calling parent class constructor with `super()` then it will get confused whether to call which parent class

problem-2 if both parent/super class contains a parameterized constructor with a same type of Formal Arg and from a sub class if you try to call a parent class constructor by using `super()` with a same actual arg --> again it will get confused whether to call which parent class

problem-3 if both a parent class contains a members

(var/method) with a same name then from a sub class if we try to call a parent class member by using super (super.member_name) then again it will get confused whether to call which parent class

- 1) what is inheritance ?
 - flow defn
 - explain extends keyword
 - explain types
- 2) what is diamond problem
 - reason-1
 - reason-2
 - reason-3
- 3) difference between this() and super()
- 4) difference between this and super
